Introduction

What is MatML?

On 01 October 1999, the National Institute of Standards and Technology (NIST) initiated the development of MatML, a markup language for the management and exchange of materials property data. At NIST, the need for such a markup language became evident in May 1997 during the development of the Ceramics WebBook¹, which includes databases of evaluated data for advanced ceramics, a guide to materials data centers and sources, and a collection of materials-related tools and resources. It was during the May 1999 ASTM-NIST Workshop on Materials Data in the Internet Age, however, when it became clear there were many independent realizations that a materials data markup language was needed. A few months later, NIST addressed this need by launching the MatML development project. The first order of business was the assembly of an international working group composed of materials data experts. The MatML Working Group's central activities were to determine the scope of MatML's application and to formulate its vocabulary and syntax. There was an especially strong emphasis during the working group discussions that: MatML ought to be flexible in the scope of its application, i.e., that it could be used to markup a wide variety of materials data from a broad range of sources; MatML's vocabulary should be materials-oriented and easy to learn; and MatML's syntax must be extensible to accommodate both alternative and unanticipated forms of materials data and their representation.

Perhaps the best way to describe MatML is by example and in contrast to HTML. Materials property data distributed on the World Wide Web in documents using hypertext markup language (HTML) present two problems for computer applications intending to use the data: interpretation and interoperability.

```
<p>
1350<br>
metal<br>
aluminum alloy<br>
ASTM B230<br>
H18<br>

Fatigue Data at High and Low Temperatures."<br>
Axial-Stress Fatigue Strength (ksi)<br>
<table>
<tr><td>23</td></tr>
<tr><td>17</td></tr>
<tr><td>15</td></tr>
</table>
```

Fig. 1: Aluminum alloy data in HTML

Figure 1 contains an HTML code fragment for aluminum alloy data. Since the data are not self-describing, one would need a complete data dictionary and glossary of terms as well as exact detailed knowledge of the document structure in order to write a computer application that uses these data without human intervention. In Figure 1, for example, it would be necessary to distinguish the descriptors of the material (1350, metal, aluminum alloy, ASTM B230, H18) from the property data (table of axial-stress fatigue strengths in ksi units). Assuming a consistent structure within and across documents from the data source, it would then be possible to parse and interpret those data programmatically for subsequent use in another computer application. In absence of tightly and consistently structured documents, a data dictionary, and a glossary of terms, however, interpretation arises as a key stumbling block for automated use of the materials property data contained in HTML documents.

If interpretation of data were not an issue, the computer application developed to parse and use the data would likely encounter serious difficulties were it to try using data from other structurally dissimilar sources. Interoperability, then, would be a limiting condition for the use of the computer application across structurally dissimilar data sources even if data dictionaries and glossaries of terms were available.

MatML addresses the problems of interpretation and interoperability for materials property data exchanged via the World Wide Web. The example given in Figure 1 might be coded as in Figure 2 and would allow an application to interpret and use materials data regardless of their sources.

¹ See: <http://www.ceramics.nist.gov/webbook/webbook.htm>

HTML tags specify only how the data are to be formatted for display and convey no description of the data themselves. While this aspect of HTML has enabled the publication of billions of web documents, it,

```

          <Unit power="-2">inch</Unit>
        </Units>
      </PropertyDetails>
    </Metadata>
  </Material>
</MatML_Doc>
```

Fig. 2: Aluminum alloy data in MatML

nonetheless, represents a serious drawback to those who wish to automate the processing of the data contained in those documents. To address this problem, the Extensible Markup Language² (XML) was developed and released by the World Wide Web Consortium³ (W3C), an international group of approximately 500 member organizations dedicated to developing common protocols that promote the evolution of the Web and ensure its interoperability.

XML enables communities, such as materials scientists and engineers in the case of MatML, to define their own domain-specific tags and document structure, i.e., they can create their own languages for data management and exchange that, in turn, permit efficient parsing and interpretation of those data via software.

The descriptive nature of the MatML tags, such as <Name>, <Class>, and <Subclass> is plainly evident, permitting the language to be far more intelligible than non-descriptive fixed tagsets such as HTML. At the same time, MatML defines a coherent and consistent document structure for its tags, which ensures that any programming language can be used to parse and process the data in whatever manner required. The formal specification for MatML 3.0 Schema, which covers syntax and semantics, is provided in Appendix A.

MatML Development History

The most important attribute of the MatML development effort was the inclusion of a broad range of input from the materials community. These individuals and groups represented private industry, government laboratories, universities, standards organizations, and professional societies, and their efforts were coordinated by NIST.

The initial strategy for MatML's development included the establishment of a working group (Table 1) that delineated the scope and specifications for the new language from which MatML was developed. On 28 April 2000, an initial working draft of the language, Annotated MatML DTD Version 1.0 (MatML 1.0), was released for comment. In response to working group feedback, a second version of MatML, Annotated MatML DTD Version 2.0 (MatML 2.0), was released on 29 March 2001. A few months later, on 26-27

Table 1: MatML Working Group (1999-2001)

June 2001, the Workshop on the Technical and Strategic Future of MatML⁴ was hosted by NIST during which open discussions were held to tabulated specific issues that required further technical refinement of the language. MatML 3.0 Schema (MatML 3.0) is an enhancement of MatML 2.0 that addresses the technical issues identified during the workshop.

Approach

The specific revisions to MatML 2.0 resulting in MatML 3.0 include: porting the language specification from XML DTD to XML Schema; eliminating redundant entry of specific types of information; overhauling the Units content model; providing a mechanism for encoding measurement uncertainty; revising the content model for Terms; modifying several element content models to improve support for encoding data for composites; and addressing a reported document validation difficulty.

Schema

From the outset of the MatML project, the working group suggested that the specification for the language, ultimately, ought to be prepared using the XML Schema Definition Language⁵ (XML Schema) rather than

⁴ Sturrock, C.P., Begley, E.F., and Kaufman, J.G., "NISTIR 6785 MatML - Materials Markup Language Workshop Report," National Institute of Standards and Technology, Gaithersburg, MD, August 2001.

⁵ See: <http://www.w3.org/2001/XMLSchema>

XML Document Type Definition (DTD). The reasons for using XML Schema include obviating notable shortcomings of DTD's and, in anticipation of MatML's acceptance testing phase, providing an improved language for software development. XML Schema, for example, provides robust support for data typing, including user-defined data types, whereas DTD's treat all data content essentially as text. Support for data types makes it easier to define permissible data values and other restrictions, to validate data, and to convert data between different data types. All of these advantages are, among other applications, essential for working with data from databases. XML Schemas, furthermore, are written in XML whereas DTD's are not. This is especially significant since it means that: XML editors and parsers can be used to edit and parse Schema files; Schemas can be manipulated using the XML Document Object Model⁶ (DOM) (The DOM views the document as a collection of objects that can be manipulated, i.e., items can be added, deleted, and modified programmatically.); and Schemas can be transformed using XML stylesheet language transformations⁷ (XSLT) (XSLT is used to transform and format documents for display.) Since the MatML development effort was initiated before the W3C had formally approved XML Schema as a recommendation, it was decided, for the short term, to define MatML 1.0 and MatML 2.0 using DTD's. On 02 May 2001, the W3C approved XML Schema 1.0. In response, MatML has been rewritten and the new version conforms to the XML Schema Definition Language.

Redundancy

Sample instance documents encoded using MatML 2.0 illustrated that descriptions of properties, measurement techniques, data sources, and parameters could be repeated many times throughout a document. This issue has been addressed by the introduction of the Metadata element, which, in addition to the previously mentioned descriptions, includes another new element, SpecimenDetails, for encoding descriptions of specimens.

Units

MatML 2.0 represented units as a simple string and permitted embedded HTML tags. MatML 3.0 uses the Units content model developed by Dr. Edward J. Shaya of NASA Goddard Space Flight Center for the eXtensible Data Format (XDF) language version 0.17⁸. This improved representation of units will permit software developers to implement units conversion applications.

Uncertainty

Previous versions of MatML did not provide for measurement uncertainty. MatML 3.0 includes a new element, Uncertainty, for encoding this information and was constructed based upon the recommendations of Dr. Ron Munro of NIST's Ceramics Division (MSEL) and Dr. Raghu Kacker of NIST's Mathematical and Computational Sciences Division in the Information Technology Laboratory.

Glossary

The Terms element in MatML 2.0 has been replaced by the Glossary element in MatML 3.0, which uses a simplified content model for encoding terms instead of the Virtual HyperGlossary^(TM)⁹ markup language.

Composites

MatML 3.0 includes the revisions proposed by the MatML Composites Working Group. These changes include recursion of the ComponentDetails element as well as new attributes on the Material element (id, layers, local_frame_of_reference) and the ComponentDetails element (id).

⁶ See: <http://www.w3.org/DOM/>

⁷ See: <http://www.w3.org/TR/xslt>

⁸ See: http://xml.gsfc.nasa.gov/DTD/XDF_017.dtd

⁹ See: http://www.vhg.org.uk/home/index_frame.html

Nesting

The MatML ASM-MSD Data Exchange Focus Group reported difficulties validating MatML 2.0 instance documents where multiple element tuples ("tuple" is a data object containing two or more data elements) were encoded within a single element (Compound, PropertyDetails, etc.). Multiple element tuples have been eliminated in MatML 3.0 and have been replaced by nested content models.

Results

Appendix A contains the formal specification for MatML Version 3.0 Schema, including detailed documentation of each element's content model. The following discussion presents a high-level overview of the language specification.

MatML_Doc

The root element for a MatML document is named MatML_Doc. The MatML_Doc element contains one or more Material elements, each of which describes a material and its properties.

Material

The information contained by the Material element is compartmentalized into five major elements:

1. BulkDetails element contains a description of the bulk material;
2. ComponentDetails element contains a description of each component of the bulk material (useful for complex materials systems such as composites or welds);
3. Metadata element contains descriptions of data found in the document;
4. Graphs element encodes two dimensional graphics;
5. Glossary element contains definitions of terms found in the document.

BulkDetails

The BulkDetails element is composed of the following elements, which are fully documented in Appendix A:

- Name contains the bulk material's name;
- Class contains the bulk material's class;
- Subclass contains the bulk material's subclass;
- Specification contains the bulk material's specification;
- Source contains the source of the bulk material;
- Form contains the form of the bulk material;
- ProcessingDetails contains a description of a step in the processing history of the bulk material;
- Geometry contains a description of the geometry of the bulk material;
- Characterization contains the characterization of the bulk material including the chemical formula, chemical composition, phase composition, and dimensional details;
- PropertyData contains data for a property of the bulk material;
- Notes contains any additional information concerning the bulk material.

ComponentDetails

The ComponentDetails element is composed of the following elements, which are fully documented in Appendix A:

- Name contains the component's name;
- Class contains the component's class;
- Subclass contains the component's subclass;
- Specification contains the component's specification;
- Source contains the source of the component;
- Form contains the form of the component;

- ProcessingDetails contains a description of a step in the processing history of the component;
- Geometry contains a description of the geometry of the component;
- Characterization contains the characterization of the component, including the chemical formula, chemical composition, phase composition, and dimensional details;
- PropertyData contains data for a property of the component;
- AssociationDetails contains a description of the relationship of the component to another component;
- Notes contains any additional information concerning the component;
- ComponentDetails contains a description of a component within the component.

Metadata

The Metadata element contains descriptions of the data sources, properties, measurement techniques, specimens, and parameters encoded within the MatML document. The Metadata element is composed of the following elements, which are fully documented in Appendix A:

- DataSourceDetails contains a description of a data source;
- PropertyDetails contains a description of a property;
- MeasurementTechniqueDetails contains a description of a measurement technique;
- SpecimenDetails contains a description of a specimen;
- ParameterDetails contains a description of a parameter.

Graphs

The Graphs element uses the W3C's Scalable Vector Graphics¹⁰ markup language (SVG) for describing two dimensional graphics and allows for three types of graphical objects: vector graphics shapes, images, and text.

Glossary

The Glossary element contains terms, each of which is encoded using the Term element. The Term element is composed of the following elements, which are fully described in Appendix A:

- Name contains the term's name;
- Definition contains the term's definition;
- Abbreviation contains the term's abbreviation(s);
- Synonym contains the term's synonym(s);
- Notes contains any additional information pertinent to the term.

Discussion

With the publication of MatML 3.0, it is now possible to address other main findings of the 2001 MatML workshop. These include:

- A good set of illustrations demonstrating the power and flexibility of MatML should be established in order to advance the widespread adoption of MatML (Appendix B);
- MatML must be tested thoroughly, involving individuals at various stages in the material development/application cycle ranging from materials specialists who select materials to designers responsible for addressing load-carrying capacity and failure limits. In addition, the needs of materials scientists exploring the fundamental structure and properties of materials, and of journal publishers disseminating materials information, must also be addressed;

¹⁰ See: <http://www.w3.org/TR/SVG/>

- At the appropriate time MatML should be recognized officially and formally via registry with XML repositories such as xml.org and/or by standards organizations such as the Object Management Group, ASTM, or ANSI;
- The overall effort should be linked with key industries, that might, via some of their applications, be in position to provide good tests for MatML and, assuming success, encourage or perhaps even require users of their information systems to use MatML as the data exchange medium.

To address some of the key strategic needs among these findings, the MatML Steering Committee (Table 2) was formed during the autumn of 2001. The

<p>J.G. Kaufman, Chairman, The Aluminum Association, Inc. (retired Vice President) Ed Begley, Lead Technical Expert, NIST Fran Cverna, ASM International Doug Fleming, Automation Creations, Inc. --

principal activities of the committee have been promotion of MatML including information dissemination, coordination of acceptance testing activities, and exploration of opportunities for MatML's long-term stewardship.

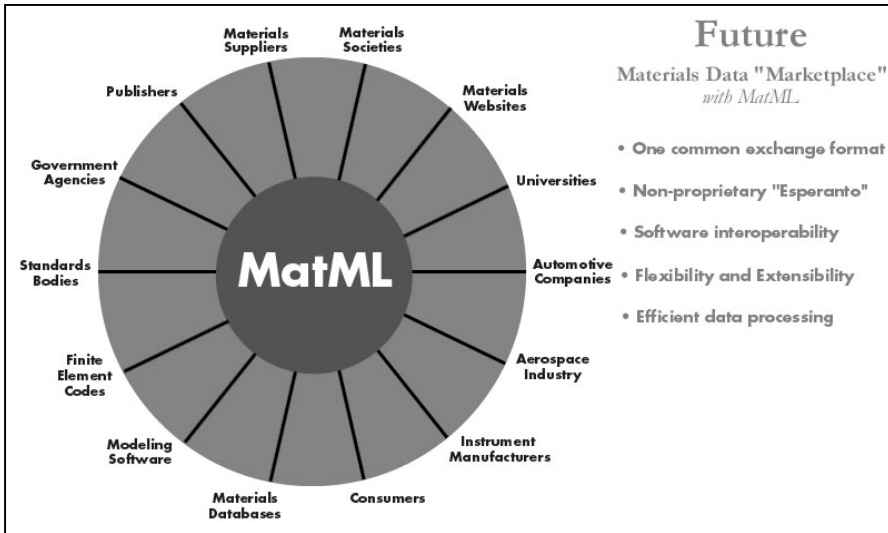

The MatML Steering Committee represents the interests of a much larger community of materials and computing professionals

interested in MatML and its objective of automating the exchange of materials property data over the Web.

Conclusion

At present, the materials data "marketplace" can be very chaotic and difficult for both providers and consumers. Until the arrival of MatML, there was no common exchange format but instead hundreds of proprietary formats that resulted in wasteful duplication of effort and poor scale-up. Also plaguing the materials data community is the absence of software interoperability, whereby one computer program, such as a finite element code, can automatically input material properties from another computer program or database without the necessity of human intervention. The present situation overall yields very inefficient data processing.

MatML will serve the materials data marketplace as a common, public-domain materials data exchange format - a non-proprietary and generic language for materials property data. With considerable built-in flexibility and extensibility as attributes of the language, MatML will provide for direct program-to-program interoperability,

efficient data processing, and rapid, reliable, and useful response to searches for materials data over the Web. Its widespread adoption will provide for powerful and malleable connection of the various materials data sources found on the Web today, as well as those to be added to the Web tomorrow.

The author especially thanks:

Jim Fowler, SIMA Program Manager (NIST), for funding and supporting the MatML effort;

Gil Kaufman, Vice President (retired), The Aluminum Association, Inc., for his leadership while chairing the MatML Steering Committee, for his insightful technical criticisms, for the pleasure of his collaboration, periodically interrupted, across three decades, and for his personal and professional guidance;

John Rumble, Measurement Services Division Chief (NIST), for his support, knowledge, insights, and generosity with his time;

Ron Munro, Physicist (MSEL), for the benefit of his wisdom and recommendations as well as his deep and broad knowledge of materials property data;

John Michopoulos, Senior Research Scientist (USNRL), for his support, enthusiasm, technical insights and, particularly, for his early adoption of MatML for use via namespace in his development of femML, the finite element modeling markup language (<http://www.istos.org/femML/>);

George Kelly, Building Environment Division Chief (BFRL) and Kent Reed, Computer Integrated Building Processes Group Leader (BFRL), for supporting the completion of this work.

Revisions

MatML Version 3.0 Schema (henceforth referred to as MatML 3.0) is an enhancement of the previously released Annotated MatML DTD Version 2.0 (henceforth referred to as MatML 2.0) and addresses the technical issues identified during the June 2001 NIST workshop entitled "The Technical and Strategic Future of MatML." In addition to these revisions, the author reorganized several content models and renamed some elements to improve the clarity of the language.

Schema

MatML 3.0 is expressed in XML Schema Definition Language and conforms to World Wide Web Consortium (W3C) <http://www.w3.org/2001/XMLSchema>.

Redundancy

Sample instance documents encoded using MatML 2.0 illustrated that descriptions of properties, measurement techniques, data sources, and parameters could be repeated many times throughout a document. This issue has been addressed by the introduction of the Metadata element, which, in addition to the previously mentioned descriptions, includes another new element, SpecimenDetails, for encoding descriptions of specimens.

Units

MatML 2.0 represented units as a simple string and permitted embedded HTML tags. MatML 3.0

uses the Units content model developed by Dr. Edward J. Shaya of NASA Goddard Space Flight Center for the eXtensible Data Format (XDF) language version 0.17 found at http://xml.gsfc.nasa.gov/DTD/XDF_017.dtd.

Uncertainty

MatML 2.0 did not provide for measurement uncertainty. MatML 3.0 includes a new element, Uncertainty, for encoding this information and was constructed based upon the recommendations of Dr. Ron Munro of NIST's Ceramics Division (MSEL) and Dr. Raghu Kacker of NIST's Mathematical and Computational Sciences Division in the Information Technology Laboratory.

Glossary

The Terms element in MatML 2.0 has been replaced by the Glossary element in MatML 3.0, which uses a simplified content model for encoding terms instead of the Virtual HyperGlossary(TM) markup language.

Composites

MatML 3.0 includes the revisions proposed by the MatML Composites Working Group. These changes include recursion of the ComponentDetails element as well as new attributes on the Material element (id, layers, local_frame_of_reference) and the ComponentDetails element (id).

Nesting

The MatML ASM-MSC Data Exchange Focus Group reported difficulties validating MatML 2.0 instance documents where multiple element tuples were encoded within a single element (Compound, PropertyDetails, etc.). Multiple element tuples have been eliminated in MatML 3.0 and have been replaced by nested content models.

```

***** Material *****

This element declares the content model for Material, which contains materials data. Material has three optional attributes.

The first attribute, id, may be used as an identification specifier for the material, which is especially useful for complex systems such as composite laminates.

The second attribute, layers, may be used to indicate the number of layers in complex systems such as composite laminates.

The third attribute, local_frame_of_reference, may be used as an identification specifier for the local material orientation relative to the

global frame of reference, which is especially useful for complex systems such as anisotropic materials.

Material is composed of the following elements.

BulkDetails contains a description of the bulk material and must occur once and only once within the Material element. For additional information, see the documentation for the BulkDetails element.

ComponentDetails contains a description of a component within the bulk material and may occur zero or more times within the Material element. ComponentDetails may be used to describe complex materials systems such as welds (e.g. the base metal, the heat affected zone, and the weld metal) or composites (e.g. the whiskers, fibers, and matrix of a fiber-reinforced composite material). For additional information, see the documentation for the ComponentDetails element.

Metadata contains descriptions of the data sources, properties, measurement techniques, specimens, and parameters which are referenced when materials property data are encoded using the PropertyData element. Metadata may occur once or not at all within the Material element. For more information, see the documentation for the Metadata element.

Graphs contains descriptions of two dimensional graphics and may occur once or not at all within the Material element. For additional information, see the documentation for the Graphs element.

Glossary contains descriptions of the material and property terms used in the document and may occur once or not at all within the Material element. For additional information, see the documentation for the Glossary element.

        <xsd:documentation>
```

***** BulkDetails *****

This element declares the content model for BulkDetails, which contains a description of the bulk material and is composed of the following elements.

Name contains the material's name and has one optional attribute, authority, for identifying an authoritative source of material names. Name must occur once and only once within the BulkDetails element.

Class contains the material's class and may occur once or not at all within the BulkDetails element.

Subclass contains the material's subclass(es) and may occur zero or more times within the BulkDetails element.

Specification contains the material's specification(s) and has one optional attribute, authority, for identifying an authoritative source of material specifications. Specification may occur zero or more times within the BulkDetails element.

Source contains the name of the source of the material and may occur once or not at all within the BulkDetails element.

Form contains the form of the material and may occur once or not at all within the BulkDetails element.

ProcessingDetails contains a description of a processing step for the material and may occur zero or more times within the BulkDetails element. For additional information, see the documentation for the ProcessingDetails element.

Geometry contains a description of the geometry of the material and may occur once or not at all within the BulkDetails element. For additional information, see the documentation for the Geometry element.

Characterization contains the characterization of the material, including the formula, chemical composition, phase composition, and dimensional details. Characterization may occur once or not at all within the BulkDetails element. For additional information, see the documentation for the Characterization element.

PropertyData contains the property data for the material and may occur zero or more times within the BulkDetails element. For additional information, see the documentation for the PropertyData element.

Notes contains any additional information concerning the bulk material and may occur once or not at all within the BulkDetails element.

***** Metadata *****

This element declares the content model for Metadata, which contains descriptions of data sources, properties, measurement techniques, specimens, and parameters, and is composed of the following elements

DataSourceDetails contains a description of a data source referenced using the PropertyData element and may occur zero or more times within the Metadata element. For additional information, see the documentation for the DataSourceDetails element.

PropertyDetails contains a description of a property for which materials data are encoded using the PropertyData element and may occur zero or more times within the Metadata element. For additional information, see the documentation for the PropertyDetails element.

MeasurementTechniqueDetails contains a description of a measurement technique referenced using the PropertyData element and may occur zero or more times within the Metadata element. For additional information, see the documentation for the MeasurementTechniqueDetails element.

SpecimenDetails contains a description of a specimen referenced using the PropertyData element and may occur zero or more times within the Metadata element. For additional information, see the documentation for the SpecimenDetails element.

ParameterDetails contains a description of a parameter referenced using the PropertyData element and may occur zero or more times within the Metadata element. For additional information, see the documentation for the ParameterDetails element.

***** ComponentDetails *****

This element declares the content model for ComponentDetails, which contains a description of a component within the bulk material and has one optional attribute, id, which may be used as an identification specifier for the component and is especially useful for complex systems such as composite laminates.

ComponentDetails is composed of the following elements.

Name contains the component's name and has one optional attribute, authority, for identifying an authoritative source of component names. Name must occur once and only once within the ComponentDetails element.

Class contains the component's class and may occur once or not at all within the ComponentDetails element.

Subclass contains the component's subclass(es) and may occur zero or more times within the ComponentDetails element.

Specification contains the component's specification(s) and has one optional attribute, authority, for identifying an authoritative source of component specifications. Specification may occur zero or more times within the ComponentDetails element.

Source contains the name of the source of the component and may occur once or not at all within the ComponentDetails element.

Form contains the form of the component and may occur once or not at all within the ComponentDetails element.

ProcessingDetails contains a description of a processing step for

the component and may occur zero or more times within the ComponentDetails element. For additional information, see the documentation for the ProcessingDetails element.

Geometry contains a description of the geometry of the component and may occur once or not at all within the ComponentDetails element. For additional information, see the documentation for the Geometry element.

Characterization contains the characterization of the component, including the formula, chemical composition, phase composition, and dimensional details. Characterization may occur once or not at all within the ComponentDetails element. For additional information, see the documentation for the Characterization element.

PropertyData contains the property data for the component and may occur zero or more times within the ComponentDetails element. For additional information, see the documentation for the PropertyData element.

AssociationDetails contains a description of a relationship of the component to another component and may occur zero or more times within the ComponentDetails element. For additional information, see the documentation for the AssociationDetails element.

Notes contains any additional information concerning the component and may occur once or not at all within the ComponentDetails element.

ComponentDetails contains a description of a component within the component and is used to support encoding of information for complex materials systems such as composites. ComponentDetails may occur zero or more times within the ComponentDetails element.

This element declares the content model for PropertyData, which contains property data. PropertyData has four attributes.

The first attribute, property, is required and references an id attribute specified in a PropertyDetails element so that the descriptive details for the property are tied to the data found in the Data element.

The second attribute, technique, is optional and references an id attribute Specified in a MeasurementTechniqueDetails element so that the Descriptive details for the measurement technique are tied to the data found In the Data element.

The third attribute, source, is optional and references an id attribute specified in a DataSourceDetails element so that the descriptive details for the data source are tied to the data found in the Data element.

The fourth attribute, specimen, is optional and references an id attribute specified in a SpecimenDetails element so that the descriptive details for the specimen are tied to the data found in the Data element.

PropertyData is composed of the following elements.

Data contains the property data and has one required attribute, format, for indicating the format of the data ("float," "integer," "string," or "exponential") found in Data. Data must occur once and only once within the PropertyData element.

Qualifier contains any qualifier(s) pertinent to the data in Data (e.g. "min," "max," etc.) and may occur once or not at all within the PropertyData element.

Uncertainty contains the measurement uncertainty(ies) of the data in Data and may occur once or not at all within the PropertyData element. For additional information, see the documentation for the Uncertainty element.

ParameterValue contains the value(s) of a parameter under which the data were determined and may occur zero or more times within the PropertyData element. For additional information, see the documentation for the ParameterValue element.

Notes contains any additional information concerning the property data and may occur once or not at all within the PropertyData element.

Note - Multiple entries in the Data, Qualifier, Uncertainty Value, and ParameterValue elements must be comma delimited and synchronized across elements, i.e., the number of entries in each of these four elements must be equal.

    <Notes>
      The authors cite V.R. Pujari et al., "Development of Improved Processing and Evaluation Methods for High
      Reliability Structural Ceramics for Advanced Heat Engine Applications, Phase I," final report, ORNL/Sub/89-SB182/1,
      NTIS Rept. No. DE93-040528, August (1993), and summarize the procedure as follows. "The cylindrical buttonhead
      specimens were machined to ORNL design with a gauge diameter of  $6.0 \pm 0.1$  mm. ...50 mm diameter, 150 mm long
      specimens... were machined as many flexure bars (3 mm by 4 mm by 50 mm) for assessment of the properties
      across the 50-mm section."

<Glossary>
  <Term>
    <Name>H18</Name>
    <Definition>
      "H18" is a code from The Aluminum Association Temper Designation System. The H is defined as "strain-hardened (wrought products only). The 1 applies to products that are strain-hardened to obtain the desired strength without supplementary thermal treatment. The 8 indicates the degree of strain-hardening and is assigned to the hardest tempers normally produced.
    </Definition>
  </Term>
  <Term>
    <Name>1350</Name>
    <Definition>
      "1350" is a code from The Aluminum Association Alloy Designation System. The first digit of the code represents the principal alloying constituent(s). The second digit indicates variations of the initial alloy. The third and fourth digits indicate individual alloy variations (the numbers have no significance but are unique). 1350 is an alloy that is pure AL (99.00% or greater). For further details, contact The Aluminum Association, 900 19th Street, N.W., Washington, D.C. 20006.

<Notes>

"A sintered electrode of TiC was used to deposit a coating on these steel coupons. The TiC electrode had 3 to 5 wt% Ni and 1 to 3 wt% Fe as binder. Deposition was carried out using a handheld gun in air at room temperature. Pulsed electrode deposition was carried out at a voltage of 50V and spark time of 10µs. The discharge capacitance used for the PES process was 450µF with a current of 25A."
